Data Structures and its Applications

TRIE Trees – An Introduction

- **TRIE** tree is a digital search tree, need not be implemented as a binary tree.
- Each node in the tree can contain 'm' pointers – corresponding to 'm' possible symbols in each position of the key.
- Generally used to store strings.

Examples:

Trie Tree -

Data Structures and its Applications

TRIE Trees – An Introduction

- A trie, pronounced “try”, is a tree that exploits some structure in the keys
 - e.g. if the keys are strings, a binary search tree would compare the entire strings but a trie would look at their individual characters
 - A trie is a tree where each node stores a bit indicating whether the string spelled out to this point is in the set

-Examples:

Data Structures and its Applications

TRIE Trees – Numeric Keys : Example2

- If the keys are numeric, there would be 10 pointers in a node.

Data Structures and its Applications

TRIE Trees – Numeric Keys : Example1

- If the keys are numeric, there would be 10 pointers in a node.
- Consider the SSN number as shown.

Name | Social Security Number (SS#)

Jack | 951-94-1654

Jill | 562-44-2169

Bill | 271-16-3624

Kathy | 278-49-1515

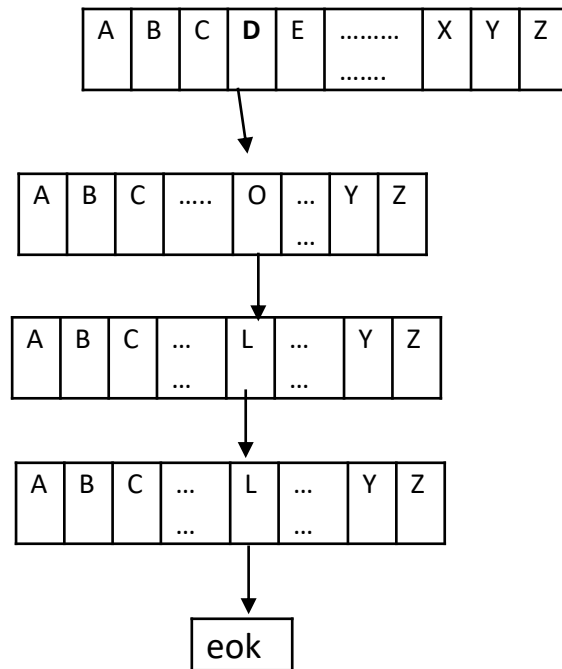

April | 951-23-7625

Data Structures and its Applications

TRIE Trees – An Introduction

- If the keys are Alphabetic, there would be 26 pointers.

Ex: The word DOLL has been stored as shown in the figure.

Data Structures and its Applications

TRIE Trees – An Introduction

- An extra pointer corresponding to eok (end of key) or a flag with each pointer indicating that it point to a record rather than to a tree node. (normally \$ symbol is used).
- A pointer in the node is associated with a particular symbol value based on its position in the node.
 - First pointer corresponds to the lowest value.
 - Second pointer to the second lowest and so forth.
- This way of implementation of a digital search tree is called a **TRIE** tree.
- The word **TRIE** is extracted from re**trie**val word.

- Tries are extremely special and useful data-structure that are based on the *prefix of a string*.
- Strings are stored in a top to bottom manner on the basis of their prefix in a TRIE.
- All prefixes of length 1 are stored at until level 1, all prefixes of length 2 are sorted at until level 2 and so on.

Suffix Trie:

- Suffix Trie is a space-efficient data structure to store a string that allows many kinds of queries to be answered quickly.
- Example:
Text is “**banana**\" data-bbox="40 578 728 801"/>

- A Trivial Algorithm for building a suffix tree.
 - Step1 : Generate all suffixes of a given text
 - Step2: Consider all suffixes as individual words and build a compressed trie.

- Example1:

Text is “**banana**\" data-bbox="95 455 418 539"/>

Following are the suffixes of Text

“**banana**/\$”

“**anana**/\$”

“**nana**/\$”

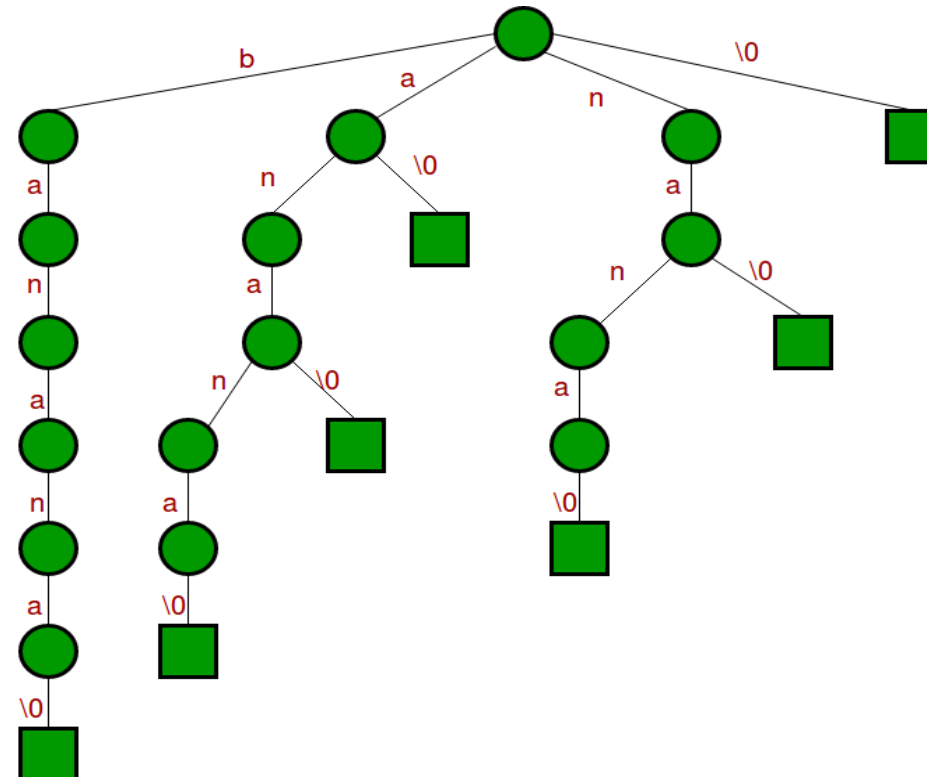

“**ana**/\$”

“**na**/\$”

“**a**/\$”

“**/**/\$”

Suffix trie

Data Structures and its Applications

Suffix Trie – Building

Example 2 : Generate the suffix trie for the word **minimize**

Step1. Generate all the suffixes of the word **minimize**.

 e
ze
ize
mize
imize
nimize
inimize
minimize

S - set of strings to
include in the suffix trie.

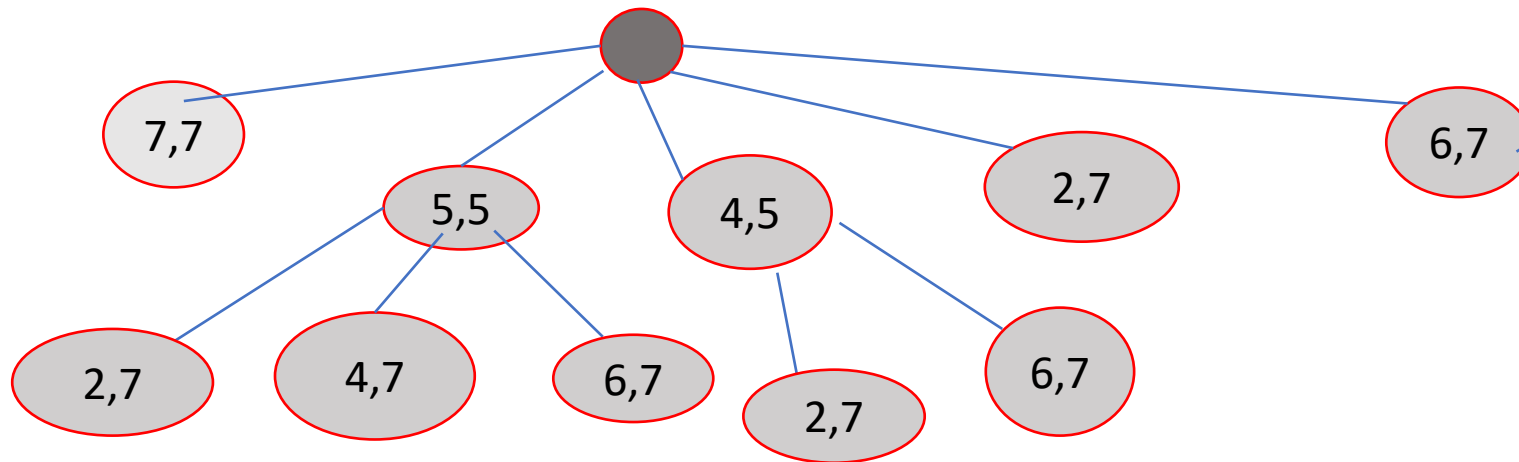

Data Structures and its Applications

Suffix Trie – Compressed Trie – using numbers

- Representation of Compressed trie using numbers - (Indexes)
- The indexes of the word is ...

0	1	2	3	4	5	6	7
m	i	n	i	m	i	z	e

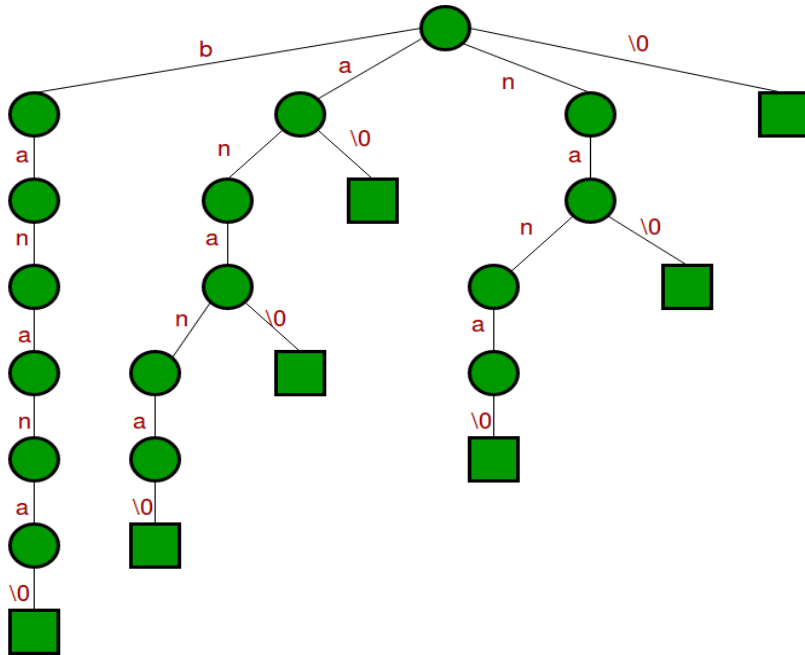

- A simple data structure for string searching
- It's a compressed Trie Tree
- Allow many fast implementations of many important string operations
- Properties of a suffix trees:
 - ✓ A suffix tree for a text X of size n from an alphabet of size d .
 - ✓ Stores all the $n(n-1)$ suffixes of X .
 - ✓ Supports arbitrary pattern matching and prefix matching queries

Example – Banana\$

Data Structures and its Applications

Suffix Trees – Introduction

- Join chains of single nodes, to get the following compressed trie, which is the Suffix tree for given text “banana\0”

Data Structures and its Applications

Search for a substring in a Suffix Tree

- 1) Starting from the first character of the pattern and root of Suffix Tree, do following for every character.
 - i) For the current character of pattern, if there is an edge from the current node of suffix tree, follow the edge.
 - ii) If there is no edge, print “pattern doesn’t exist in text” and return.
- 2) If all characters of pattern have been processed, i.e., there is a path from root for characters of the given pattern, then print “Pattern found”.

Applications:

- English dictionary
- Predictive text
- Auto-complete dictionary found on Mobile phones and other gadgets.

Advantages:

- Faster than BST
- Printing of all the strings in the alphabetical order easily.
- Prefix search can be done (Auto complete).

Disadvantages:

- Need for a lot of memory to store the strings,
- Storing of too many node pointers.
